

ADS833x Low-Power, 16-Bit, 500-kSPS, 4-/8-Channel Unipolar Input Analog-to-Digital Converters With Serial Interface

1 Features

- Low-Power, Flexible Supply Range:
 - 2.7-V to 5.5-V Analog Supply
 - 8.7 mW (250 kSPS in Auto-NAP Mode, $V_A = 2.7\text{ V}$, $V_{BD} = 1.65\text{ V}$)
 - 14.2 mW (500 kSPS, $V_A = 2.7\text{ V}$, $V_{BD} = 1.65\text{ V}$)
- Up to 500-kSPS Sampling Rate
- Excellent DC Performance:
 - $\pm 1.2\text{ LSB}$ Typical, $\pm 2\text{ LSB}$ Maximum INL at 2.7 V
 - $\pm 0.6\text{ LSB}$ Typical, $-1/1.5\text{ LSB}$ Maximum DNL at 2.7 V
 - 16-Bit NMC Over Temperature
- Excellent AC Performance at 5 V , $f_{IN} = 1\text{ kHz}$:
 - 91.5-dB SNR, 101-dB SFDR, -100-dB THD
- Flexible Analog Input Arrangement:
 - On-Chip 4-/8-Channel Mux With Breakout
 - Auto/Manual Channel Select and Trigger
- Other Hardware Features:
 - On-Chip Conversion Clock (CCLK)
 - Software/Hardware Reset
 - Programmable Status/Polarity EOC/ $\overline{\text{INT}}$
 - Daisy-Chain Mode
 - Global $\overline{\text{CONVST}}$ (Independent of $\overline{\text{CS}}$)
 - Deep, Nap, and Auto-NAP Powerdown Modes
 - SPI™/DSP Compatible Serial Interface
 - Separate I/O Supply: 1.65 V to V_A
 - SCLK up to 40 MHz ($V_A = V_{BD} = 5\text{ V}$)
- 24-Pin 4-mm x 4-mm VQFN and 24-Pin TSSOP Packages

2 Applications

- Communications
- Transducer Interfaces
- Medical Instruments
- Magnetometers
- Industrial Process Controls
- Data Acquisition Systems
- Automatic Test Equipment

3 Description

The ADS8331 is a low-power, 16-bit, 500-k samples-per-second (SPS) analog-to-digital converter (ADC) with a unipolar, 4-to-1 multiplexer (mux) input. The device includes a 16-bit capacitor-based successive approximation register (SAR) ADC with inherent sample and hold.

The ADS8332 is based on the same core and includes a unipolar 8-to-1 input mux. Both devices offer a high-speed, wide-voltage serial interface and are capable of daisy-chain operation when multiple converters are used.

These converters are available in 24-pin, 4×4 QFN and 24-pin TSSOP packages and are fully specified for operation over the industrial -40°C to 85°C temperature range.

Device Information⁽¹⁾

PART NUMBER	PACKAGE	BODY SIZE (NOM)
ADS833x	VQFN (24)	4.00 mm x 4.00 mm
	TSSOP (24)	7.80 mm x 4.40 mm

(1) For all available packages, see the orderable addendum at the end of the data sheet.

6 Pin Configuration and Functions

- (1) NC = No internal connection (ADS8331 only).
(2) Connect thermal pad to analog ground.
(3) NC = No internal connection (ADS8331 only).

Pin Functions: ADS8331

NAME	PIN		I/O	DESCRIPTION
	TSSOP	VQFN		
ADCIN	21	18	I	ADC input
AGND	20	17	—	Analog ground
DGND	14	11	—	Digital interface ground
COM	23	20	I	Common ADC input (usually connected to AGND)
CONVST	15	12	I	Conversion start. Freezes sample and hold, starts conversion.

Pin Functions: ADS8331 (continued)

PIN			I/O	DESCRIPTION
NAME	TSSOP	VQFN		
EOC/ $\overline{\text{INT}}$ /CDI	9	6	O/O/I	Status output. If programmed as end-of-conversion (EOC), this pin is low (default) when a conversion is in progress. If programmed as an interrupt ($\overline{\text{INT}}$), this pin is low (default) after the end of conversion and returns high after FS/ $\overline{\text{CS}}$ goes low. The polarity of EOC or $\overline{\text{INT}}$ is programmable. This pin can also be used as a chain data input (CDI) when operated in daisy-chain mode.
FS/ $\overline{\text{CS}}$	11	8	I	Frame sync signal for DSP (such as TMS320™ DSP) or chip select input for SPI.
IN _[0:3]	1-3, 24	21-24	I	Mux inputs
NC	4-7	1-4	—	No connection
MUXOUT	22	19	O	Mux output
REF+	18	15	I	External reference input
REF–	19	16	—	External reference ground (connect to AGND through an individual via on the printed-circuit-board)
$\overline{\text{RESET}}$	8	5	I	External reset (active low)
SCLK	10	7	I	SPI clock for serial interface
SDI	12	9	I	SPI serial data in
SDO	13	10	O	SPI serial data out
VA	17	14	—	Analog supply, 2.7 V to 5.5 V
VBD	16	13	—	Digital interface supply

Pin Functions: ADS8332

PIN			I/O	DESCRIPTION
NAME	TSSOP	VQFN		
ADCIN	21	18	I	ADC input

7 Specifications

7.1 Absolute Maximum Ratings

Over operating free-air temperature range, unless otherwise noted.⁽¹⁾

		MIN	MAX	UNIT
Voltage	IN _X , MUXOUT, ADCIN, REF+ to AGND	–0.3	VA + 0.3	V
	COM, REF– to AGND	–0.3	0.3	
	VA to AGND	–0.3	7	
	VBD to DGND	–0.3	7	
	AGND to DGND	–0.3	0.3	
Digital input voltage to DGND		–0.3	VBD + 0.3	V
Digital output voltage to DGND		–0.3	VBD + 0.3	V
4 × 4 QFN-24 Package	Power dissipation		(T _J Max – T _A)/R _{θJA}	W
	R _{θJA} thermal impedance		47	°C/W
TSSOP-24 Package	Power dissipation		(T _J Max – T _A)/θ _{JA}	W
	R _{θJA} thermal impedance		47	°C/W
Operating free-air temperature, T _A		–40	85	°C
Junction temperature, T _J Max			150	°C
Storage temperature range, T _{stg}		–65	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

7.2 ESD Ratings

		VALUE	UNIT
V _(ESD) Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
	Charged-device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±500	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.
(2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

7.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

		MIN	NOM	MAX	UNIT
VA	Analog supply voltage	2.7	3	3.6	V
VBD	Digital supply voltage	1.65	3	VA + 0.2	V

7.4 Thermal Information

THERMAL METRIC ⁽¹⁾		ADS833x		UNIT
		RGE (VQFN)	PW (TSSOP)	
		24 PINS	24 PINS	
R _{θJA}	Junction-to-ambient thermal resistance	31.9	78.3	°C/W
R _{θJC(top)}	Junction-to-case (top) thermal resistance	29.2	12.1	°C/W
R _{θJB}	Junction-to-board thermal resistance	8.7	33.8	°C/W
Ψ _{JT}	Junction-to-top characterization parameter	0.3	0.3	°C/W
Ψ _{JB}	Junction-to-board characterization parameter	8.7	33.5	°C/W
R _{θJC(bot)}	Junction-to-case (bottom) thermal resistance	2.25	NA	°C/W

- (1) For more information about traditional and new thermal metrics, see the *Semiconductor and IC Package Thermal Metrics* application report, [SPRA953](#).

8 Detailed Description

8.1 Overview

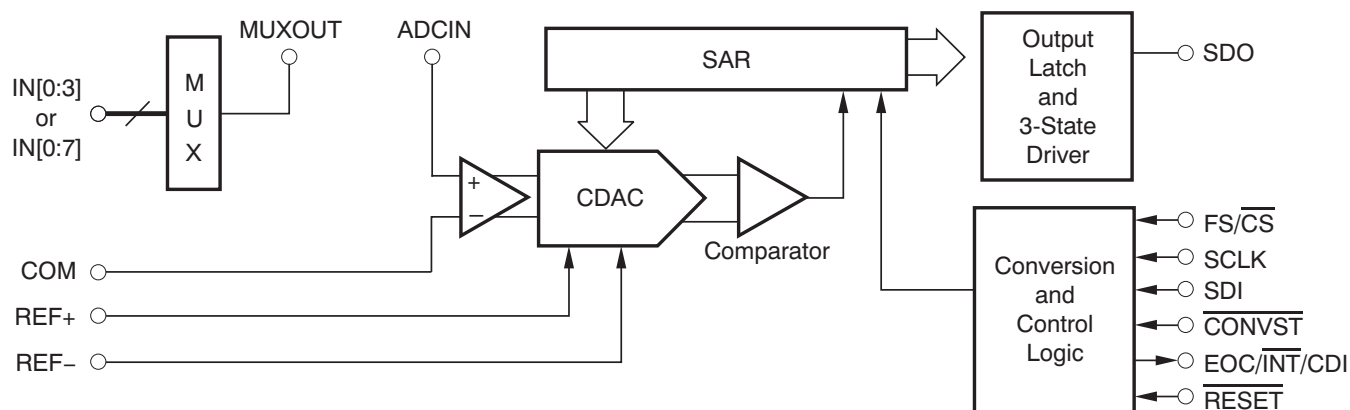

The ADS833x is a high-speed, low-power, successive approximation register (SAR) analog-to-digital converter (ADC) that uses an external reference. The architecture is based on charge redistribution, which inherently includes a sample/hold function.

The ADS833x has an internal clock that is used to run the conversion. However, the ADS833x can be programmed to run the conversion based on the external serial clock (SCLK).

The analog input to the ADS833x is provided to two input pins: one of the IN_x input channels and the shared COM pin. When a conversion is initiated, the differential input on these pins is sampled on the internal capacitor array. While a conversion is in progress, both IN_x and COM inputs are disconnected from any internal function.

The ADS8331 has four analog inputs while the ADS8332 has eight inputs. All inputs share the same common pin, COM. Both the ADS8331 and ADS8332 can be programmed to select a channel manually or can be programmed into the auto channel select mode to sweep through the input channels automatically.

8.2 Functional Block Diagram

8.3 Feature Description

8.3.1 Signal Conditioning

The ADS833x has the flexibility to add signal conditioning between the MUXOUT and ADCIN pins, such as a programmable gain amplifier (PGA) or filter. This feature reduces the system component count and cost because each input channel does not require separate signal conditioning circuits, especially if the source impedance connected to each channel is similar in value.

8.3.2 Analog Input

When the converter enters the hold mode, the voltage difference between the IN_x and COM inputs is captured on the internal capacitor array. The voltage on the COM pin is limited from (AGND – 0.2 V) to (AGND + 0.2 V). This limitation allows the ADS833x to reject small signals that are common to both the IN_x and COM inputs. The IN_x inputs have a range of –0.2 V to ($V_A + 0.2$ V). The input span of ($IN_x - COM$) is limited to 0 V to V_{REF} .

The peak input current through the analog inputs depends upon a number of factors: reference voltage, sample rate, input voltage, and source impedance. The current flowing into the ADS833x charges the internal capacitor array during the sample period. After this capacitance has been fully charged, there is no further input current. The source of the analog input voltage must be able to charge the maximum input capacitance (45 pF) to a 16-bit settling level within the minimum acquisition time (238 ns). When the converter goes into hold mode, the input impedance is greater than 1 GΩ.

Feature Description (continued)

Take care when regarding the absolute analog input voltage. To maintain linearity of the converter, the IN_X inputs, the COM input, and the input span of ($IN_X - COM$) should be within the limits specified. If these inputs are outside of these ranges, the linearity of the converter may not meet specifications. To minimize noise, low-bandwidth input signals with low-pass filters should be used. Ensure that the output impedance of the sources driving the IN_X and COM inputs are matched, as shown in Figure 34. If this matching is not observed, the two inputs could have different settling times, which may result in an offset error, gain error, and linearity error that change with temperature and input voltage.

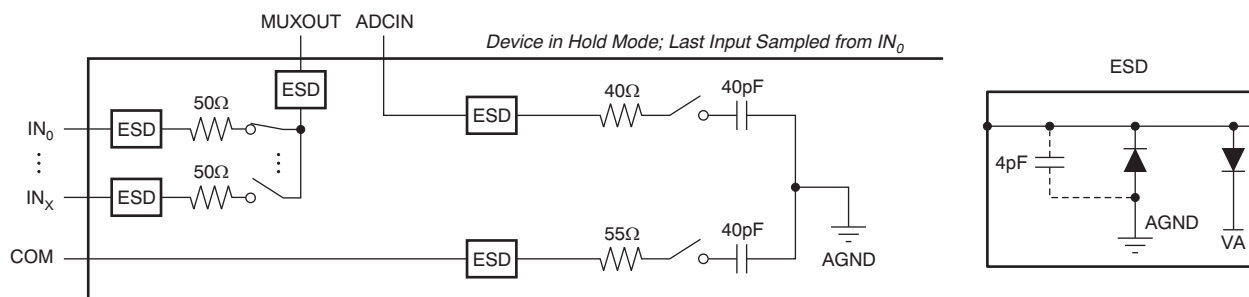

Figure 34. Input Equivalent Circuit

8.3.2.1 Driver Amplifier Choice

To take advantage of the high sample rate offered by the ADS833x, the analog inputs to the converter should be driven with low-noise operational amplifiers (op amps), such as the OPA365, OPA211, OPA827, or THS4031. TI recommends a RC filter at each of the input channels to low-pass filter noise generated by the input driving sources. These channels can accept unipolar signals with voltages between IN_X and COM in the range of 0 V to V_{REF} . If RC filters are not used between the op amps and the input channels, the minimum –3-dB bandwidth required by the driving op amps for the sampled signals to settle to within 1/2 LSB of the final voltage can be calculated using Equation 1:

$$f_{-3dB} \geq \frac{(n + 1) \times \ln(2)}{2\pi \times t_{SAMPLE_MIN}}$$

where

- n = resolution of the converter ($n = 16$ for the ADS833x).
- t_{SAMPLE_MIN} = minimum acquisition time.

(1)

The minimum value of t_{SAMPLE} in *Electrical Characteristics: $VA = 2.7 V$* and *Electrical Characteristics: $VA = 5 V$* is 238 ns (3 CCLKs with the internal oscillator at 12.6 MHz). Substituting these values for n and t_{SAMPLE_MIN} into Equation 1 shows $f_{-3 dB}$ must be at least 7.9 MHz. This bandwidth can be relaxed if the acquisition time is increased or an RC filter is added between the driving operational amplifier and the corresponding input channel (see Texas Instruments' Application Report, *Determining Minimum Acquisition Times for SAR ADCs When a Step Function is Applied to the Input* (SBAA173) and associated references for additional information, available for download at www.ti.com). The OPA365 used in the source-follower (unity-gain) configuration is shown in Figure 35 with recommended values for the RC filter.

Figure 35. Unipolar Input Drive Configuration

Feature Description (continued)

8.3.2.2 Bipolar to Unipolar Driver

In systems where the input signal is bipolar, op amps such as the [OPA365](#) and [OPA211](#) can be used in the inverting configuration with a DC bias applied to the noninverting input to keep the input signal to the ADS833x within its rated operating voltage range. TI also recommends this configuration when the ADS833x is used in signal-processing applications where good SNR and THD performance is required. The DC bias can be derived from low-noise reference voltage ICs such as the [REF5025](#) or [REF5040](#). The input configuration shown in [Figure 36](#) is capable of delivering better than 91-dB SNR and –99-dB THD at an input frequency of 1 kHz. If bandpass filters are used to filter the input to the driving operational amplifier, the signal swing at the input of the bandpass filter should be small enough to minimize the distortion introduced by the filter. In these cases, the gain of the circuit shown in [Figure 36](#) can be increased to maintain a large enough input signal to the ADS833x to keep the system SNR as high as possible.

Figure 36. Bipolar Input Drive Configuration

8.4 Device Functional Modes

8.4.1 Reference

The ADS833x can operate with an external reference with a range from 1.2 V to 4.2 V. A clean, low-noise reference voltage on this pin is required to ensure good converter performance. A low-noise band-gap reference such as the [REF5025](#) or [REF5040](#) can be used to drive this pin. A 10-μF ceramic bypass capacitor is required between the REF+ and REF– pins of the converter. This capacitor should be placed as close as possible to the pins of the device. The REF– pin should not be connected to the AGND pin of the converter; instead, the REF– pin must be connected to the analog ground plane with a separate via.

8.4.2 Converter Operation

The ADS833x has an internal oscillator that can be used as the conversion clock (CCLK) source. The minimum frequency of this oscillator is 10.5 MHz. The internal oscillator is only active during the conversion period unless the converter is using Auto-Trigger and/or Auto-NAP modes. The minimum acquisition/sampling time for the ADS833x is 3 CCLKs (250 ns with a 12-MHz conversion clock), while the minimum conversion time is 18 CCLKs (1500 ns with a 12-MHz conversion clock).

As shown in [Figure 37](#), the ADS833x can also be programmed to run conversions using the external serial clock (SCLK). This feature allows system designers to achieve system synchronization. Each rising edge of SCLK toggles the state of the conversion clock (CCLK), which reduces the frequency of SCLK by a factor of two before it is used as CCLK. For example, a 21-MHz SCLK provides a 10.5-MHz CCLK. If the start of a conversion must occur on a specific rising edge of SCLK when the external serial clock is used for the conversion clock (and Manual-Trigger mode is enabled), a minimum setup time of 20 ns between the falling edge of CONVST and the rising edge of SCLK must be met. This timing ensures the conversion is completed in 18 CCLKs (36 SCLKs).

The duty cycle of SCLK is not critical, as long as the minimum high and low times (11 ns for VA = 5 V) are satisfied. Because the ADS833x is designed for high-speed applications, a high-frequency serial clock must be supplied to maintain the high throughput of the interface. This requirement can be accomplished if the period of SCLK is at most 1 μs when SCLK is used as the conversion clock (CCLK). The 1-μs maximum period for SCLK is also set by the leakage of charge from the capacitors in the capacitive digital-to-analog converter (CDAC) block in the ADS833x. If SCLK is used as the conversion clock, the SCLK source must have minimal rise/fall times and low jitter to provide the best converter performance.

Device Functional Modes (continued)

Figure 37. Conversion Clock Source

8.4.2.1 Manual Channel Select Mode

Manual Channel Select mode is enabled through the Configuration register (CFR) by setting the CFR_D11 bit to 0 (see Table 5). The acquisition process starts with selecting an input channel. This selection is done by writing the desired channel number to the Command register (CMR); see Table 4 for further details. The associated timing diagram is shown in Figure 38.

Figure 38. Manual Channel Select Timing

8.4.2.2 Auto Channel Select Mode

Channel selection can also be done automatically if Auto Channel Select mode (default) is enabled (CFR_D11 = 1). If the device is programmed for Auto Channel Select mode, then signals from all channels are acquired in a fixed order. In Auto Channel Select mode, the first conversion after entering this mode is always from the channel of the last conversion completed before this mode is enabled. The channels are then sequentially scanned up to and including the last channel (that is, channel 3 for the ADS8331 and channel 7 for the ADS8332) and then back to the channel that started the sequence. For example, if the last channel used in the conversion before enabling Auto Channel Select mode was channel 2, the sequence for the ADS8332 would be: 2, 3, 4, 5, 6, 7, 2, and so forth, as shown in Figure 39. If the last channel in Manual Channel Select mode happened to be channel 7, the sequence would be: 7, 7, 7, and so forth. Figure 40 shows when the next channel in the sequence activates during Auto Channel Select cycle mode. This timing allows the next channel to settle before it is acquired. This automatic sequencing stops the cycle after CFR_D11 is set to 0.

Device Functional Modes (continued)

Figure 39. Auto Channel Select for the ADS8332

Figure 40. Channel-Number Update in Auto Channel Select Mode Timing

Device Functional Modes (continued)

8.4.2.3 Start of a Conversion

The end of acquisition is the same as the start of a conversion. This process is initiated by bringing the $\overline{\text{CONVST}}$ pin low for a minimum of 40 ns. After the minimum requirement has been met, the $\overline{\text{CONVST}}$ pin can be brought high. $\overline{\text{CONVST}}$ acts independently of FS/CS so it is possible to use one common $\overline{\text{CONVST}}$ for applications that require simultaneous sample/hold with multiple converters. The ADS833x switches from sample to hold mode on the falling edge of the $\overline{\text{CONVST}}$ signal. The ADS833x requires 18 conversion clock (CCLK) cycles to complete a conversion. The conversion time is equivalent to 1500 ns with a 12-MHz internal clock. The minimum time between two consecutive $\overline{\text{CONVST}}$ signals is 21 CCLKs.

A conversion can also be initiated without using $\overline{\text{CONVST}}$ if the ADS833x is programmed for Auto-Trigger mode (CFR_D9 = 0). When the converter is configured in this mode, and with CFR_D8 = 0, the next conversion is automatically started three conversion clocks (CCLK) after the end of a conversion. These three conversion clocks (CCLK) are used for the acquisition time. In this case, the time to complete one acquisition and conversion cycle is 21 CCLKs. Table 1 summarizes the different conversion modes.

Table 1. Different Types of Conversion

MODE	SELECT CHANNEL	START CONVERSION
Automatic	Auto Channel Select⁽¹⁾	Auto-Trigger Mode
	No need to write channel number to CMR. Use internal sequencer for ADS833x.	Start a conversion based on conversion clock CCLK
Manual	Manual Channel Select	Manual-Trigger Mode
	Write channel number to CMR	Start a conversion with $\overline{\text{CONVST}}$

(1) Auto channel select should be used with Auto-Trigger mode and TAG bit output enabled.

Manual Channel select with Auto-Trigger mode enabled is generally used when continuous conversions from a single channel are desired. In this mode, cycling the input mux to change the channel requires that conversions are halted by setting the converter to Manual-Trigger mode. When the proper input channel is selected, the converter can be placed back to Auto-Trigger mode to continue continuous conversions from the new channel.

8.4.2.4 Status Output Pin (EOC/ $\overline{\text{INT}}$)

The status output pin is programmable. It can be used as an EOC output (CFR_D[7:6] = 11) where the low time is equal to the conversion time. When the status pin is programmed as EOC and the polarity is set as active low, the pin works in the following manner: the EOC output goes low immediately following $\overline{\text{CONVST}}$ going low with Manual-Trigger mode enabled. EOC stays low throughout the conversion process and returns high when the conversion has ended. If Auto-Trigger mode is enabled, the EOC output remains high for three conversion clocks (CCLK) after the previous rising edge of EOC.

This status pin can also be used as an interrupt output, $\overline{\text{INT}}$ (CFR_D[7:6] = 10), which is set low at the end of a conversion, and is brought high (cleared) by the next read cycle. The polarity of this pin, whether used as EOC or $\overline{\text{INT}}$, is programmable through the CFR_D7 bit.

8.4.2.5 Power-Down Modes and Acquisition Time

There are three power-down modes that reduce power dissipation: Nap, Deep, and Auto-NAP. The first two, Nap and Deep Power-Down modes, are enabled/disabled by bits CFR_D3 and CFR_D2, respectively, in the Configuration register (see [Table 5](#) for details).

Deep Power-Down mode provides maximum power savings. When this mode is enabled, the analog core in the converter is shut down, and the analog supply current falls from 6.6 mA ($V_A = 5\text{ V}$) to 1 μA in 2 μs . The wake-up time from Deep Power-Down mode is 1 μs . The device can wake up from Deep Power-Down mode by either disabling this mode, issuing the wake-up command, loading the default value into the CFR, or performing a reset (either with the software reset command, CFR_D0 bit, or the external reset). See [Table 4](#) and [Table 5](#) along with the [Reset Function](#) section for further information.

In Nap Power-Down mode, the bias currents for the analog core of the device are significantly reduced. Because the bias currents are not completely shut off, the ADS833x can wake up from this power-down mode much faster than from Deep Power-Down mode. After Nap Power-Down mode is enabled, the analog supply current falls from 6.6 mA ($V_A = 5\text{ V}$) to 0.39 mA in 200 ns. The wake-up time from this mode is three conversion clock cycles (CCLK). The device can wake up from Nap Power-Down mode in the same manner as waking up from Deep Power-Down mode.

The third power-down mode, Auto-NAP, is enabled/disabled by bit CFR_D4 in the Configuration register (see [Table 5](#) for details). Once this mode is enabled, the device is controlled by the digital core logic on the chip. The device is automatically placed into Nap Power-Down mode after the next end of conversion (EOC). The analog supply current falls from 6.6mA ($V_A = 5\text{ V}$) to 0.39 mA in 200 ns. A conversion start wakes up the device in three conversion clock cycles. Issuing the wake-up command, loading the default value into the CFR, disabling Auto-NAP Power-Down mode, issuing a manual channel select command, or resetting the device can wake the ADS833x from Auto-NAP Power-Down mode. A comparison of the three power-down modes is listed in [Table 2](#).

Table 2. Comparison of Power-Down Modes

TYPE OF POWER-DOWN	POWER CONSUMPTION ($V_A = 5\text{ V}$)	POWER-DOWN BY:	POWER-DOWN TIME	WAKEUP BY:	WAKE-UP TIME	ENABLE
Normal operation	6.6 mA	—	—	—	—	—
Deep power-down	1 μA	Setting CFR_D2	2 μs	Wakeup command 1011b	1 μs	Set CFR_D2
Nap power-down	0.39 mA	Setting CFR_D3	200 ns	Wakeup command 1011b	3 CCLKs	Set CFR_D3
Auto-NAP power-down	0.39 mA	EOC (end of conversion)	200 ns	$\overline{\text{CONVST}}$, any channel select command, default command 1111b, or wakeup command 1011b.	3 CCLKs	Set CFR_D4

The default acquisition time is three conversion clock (CCLK) cycles. [Figure 41](#) shows the timing diagram for $\overline{\text{CONVST}}$, EOC, and Auto-NAP power-down signals in Manual-Trigger mode. As shown in the diagram, the device wakes up after a conversion is triggered by the $\overline{\text{CONVST}}$ pin going low. However, a conversion is not yet started at this time. The conversion start signal to the analog core of the chip is internally generated no less than six conversion clock (CCLK) cycles later, to allow at least three CCLKs for wake up and three CCLKs for acquisition. The ADS833x enters Nap Power-Down mode one conversion cycle after the end of conversion (EOC).

Figure 41. Timing for $\overline{\text{CONVST}}$, EOC, and Auto-NAP Power-Down Signals in Manual-Trigger Mode (Three Conversion Clock Cycles for Acquisition)

The ADS833x can support sampling rates of up to 500 kSPS in Auto-Trigger mode. This rate is selectable by programming the CFR_D8 bit in the Configuration register. In 500-kSPS mode, consecutive conversion start pulses to the analog core are generated 21 conversion clock cycles apart. In 250-kSPS mode, consecutive conversion-start pulses are 42 conversion clock cycles apart. The Nap and Deep Power-Down modes are available with either sampling rate; however, Auto-NAP mode is available only with a sampling rate of 250 kSPS when Auto-Trigger mode is enabled. The analog core cannot be powered down when the Auto-NAP mode sampling rate is 500 kSPS because at that rate, there is no period of time when the analog core is not actively being used.

Figure 42 shows the timing diagram for conversion start and Auto-NAP power-down signals for a 250-kSPS sampling rate in Auto-Trigger mode. For a 16-bit ADC output word, consecutive new conversion start pulses are generated $2 \times (18 + 3)$ cycles apart. NAP_ACTIVE (the signal to power down the analog core in Nap and Auto-NAP modes) goes low six $(3 + 3)$ conversion clock cycles before the conversion start falling edge, thus powering up the analog core. It takes three conversion clock cycles after NAP_ACTIVE goes low to power up the analog core. The analog core is powered down a cycle after the end of a conversion. For a 16-bit ADC with a 500-kSPS sampling rate and three conversion clock cycle sampling, consecutive conversion start pulses are generated 21 conversion clock cycles apart.

Figure 42. Timing for Conversion Start and Auto-NAP Power-Down Signals in Auto-Trigger Mode (250-kSPS Sampling and Three Conversion Clock Cycles for Acquisition)

Timing diagrams for reading from the ADS833x with various trigger and power-down modes are shown in Figure 43 through Figure 45. The total (acquisition + conversion) times for the different trigger and power-down modes are listed in Table 3.

Table 3. Total Acquisition + Conversion Times

MODE	ACQUISITION + CONVERSION TIME
Auto-Trigger at 500 kSPS	= 21 CCLK
Manual-Trigger	≥ 21 CCLK
Manual-Trigger with Deep Power Down	≥ 4 SCLK + 1 μs + 3 CCLK + 18 CCLK + 16 SCLK + 2 μs
Manual-Trigger with Nap Power Down	≥ 4 SCLK + 3 CCLK + 3 CCLK + 18 CCLK + 16 SCLK + 200 ns
Manual-Trigger with Auto-NAP Power Down	≥ 4 SCLK + 3 CCLK + 3 CCLK + 18 CCLK + 1 CCLK + 200 ns (using wakeup to resume)
	≥ 3 CCLK + 3 CCLK + 18 CCLK + 1 CCLK + 200 ns (using $\overline{\text{CONVST}}$ to resume)

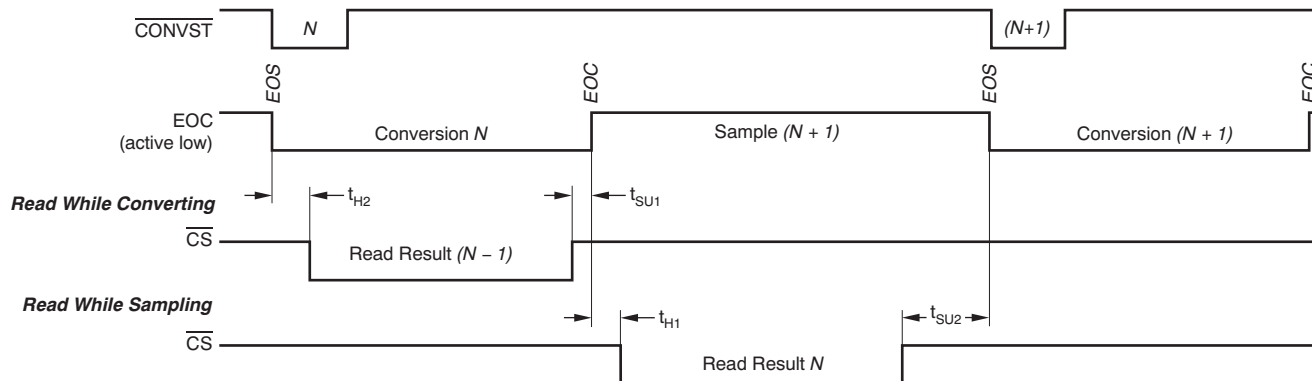

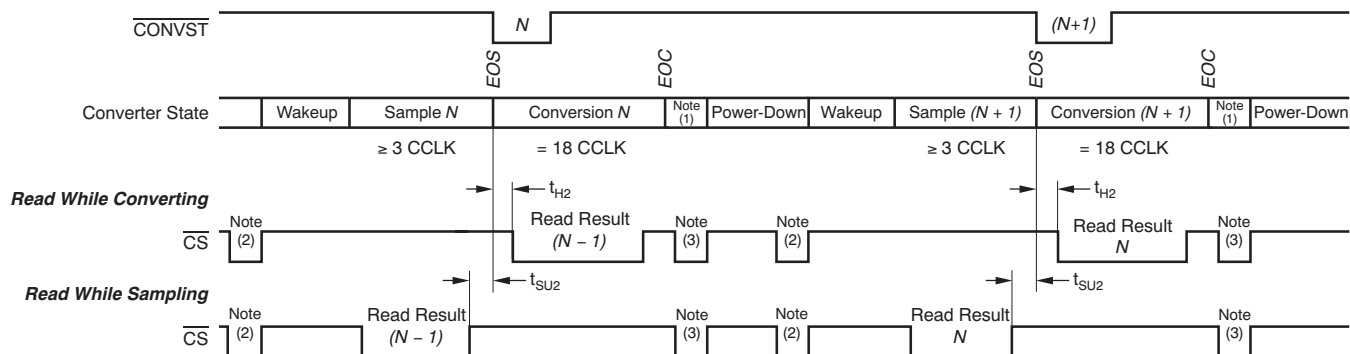

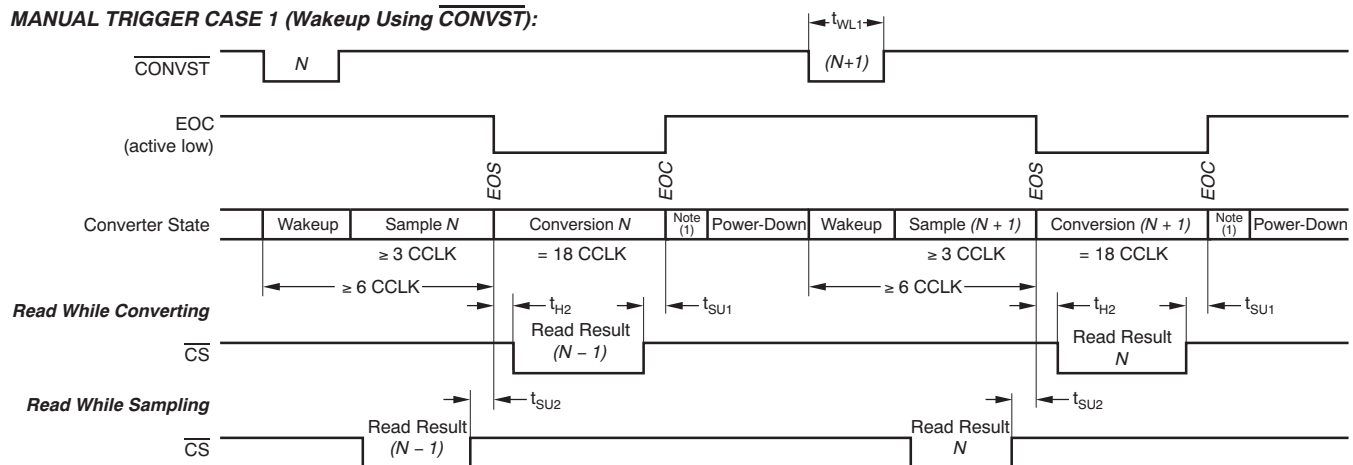

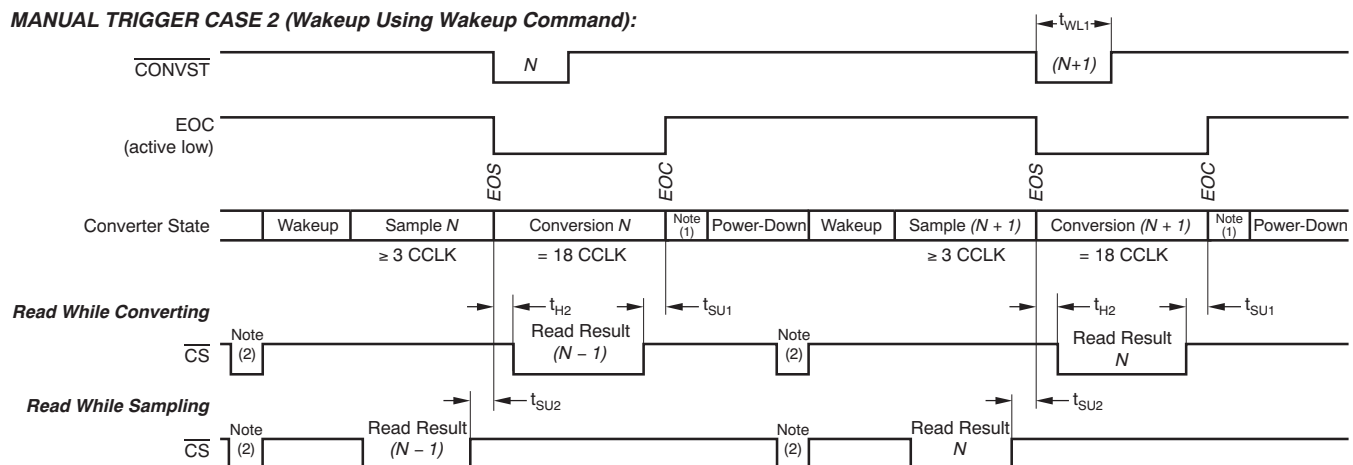

Figure 43. Read While Converting vs Read While Sampling (Manual-Trigger Mode)

- (1) Converter is in acquisition mode between end of conversion and activation of Nap or Deep Power-Down mode.
- (2) Command on SDI pin to wake-up converter (minimum of four SCLKs).
- (3) Command on SDI pin to place converter into Nap or Deep Power-Down mode (minimum of 16 SCLKs).

8.5 Programming

8.5.1 Digital Interface

The serial interface is designed to accommodate the latest high-speed processors with an SCLK frequency of up to 40 MHz ($V_A = V_{BD} = 5\text{ V}$). Each cycle starts with the falling edge of FS/ $\overline{\text{CS}}$. The internal data register content, which is made available to the output register at the end of conversion, is presented on the SDO output pin on the falling edge of FS/ $\overline{\text{CS}}$. The first bit is the most significant bit (MSB). The output data bits are valid on the falling edge of SCLK with the t_{D2} delay (see the [Timing Requirements: \$V_A = 2.7\text{ V}\$](#) and [Timing Characteristics: \$V_A = 5\text{ V}\$](#)) so that the host processor can read the data on the falling edge. Serial data input is also read on the falling edge of SCLK.

The complete serial I/O cycle starts after the falling edge of FS/ $\overline{\text{CS}}$ and ends 16 falling edges of SCLK later (see NOTE). The serial interface works with CPOL = 1, CPHA = 0. This setting means the falling edge of FS/ $\overline{\text{CS}}$ may fall while SCLK is high. The same timing relaxation applies to the rising edge of FS/ $\overline{\text{CS}}$ where SCLK may be high or low as long as the last SCLK falling edge happens before the rising edge of FS/ $\overline{\text{CS}}$.

Programming (continued)

NOTE

There are cases where a cycle can be anywhere from 4 SCLKs up to 24 SCLKs, depending on the read mode combination. See [Table 4](#) for details.

8.5.1.1 Internal Register

The internal register consists of two parts: four bits for the Command register (CMR) and 12 bits for the Configuration register (CFR).

Table 4. Command Set Defined by Command Register (CMR)⁽¹⁾

D[15:12]	HEX	COMMAND	D[11:0]	WAKE UP FROM AUTO- NAP	MINIMUM SCLKs REQUIRED	R/W
0000b	0h	Select analog input channel 0	Don't care	Y	4	W
0001b	1h	Select analog input channel 1	Don't care	Y	4	W
0010b	2h	Select analog input channel 2	Don't care	Y	4	W
0011b	3h	Select analog input channel 3	Don't care	Y	4	W
0100b	4h	Select analog input channel 4 ⁽²⁾	Don't care	Y	4	W
0101b	5h	Select analog input channel 5 ⁽²⁾	Don't care	Y	4	W
0110b	6h	Select analog input channel 6 ⁽²⁾	Don't care	Y	4	W
0111b	7h	Select analog input channel 7 ⁽²⁾	Don't care	Y	4	W
1000b	8h	Reserved	Reserved	—	—	—
1001b	9h	Reserved	Reserved	—	—	—
1010b	Ah	Reserved	Reserved	—	—	—
1011b	Bh	Wake up	Don't care	Y	4	W
1100b	Ch	Read CFR	Don't care	—	16	R
1101b	Dh	Read data	Don't care	—	16	R
1110b	Eh	Write CFR	CFR Value	—	16	W
1111b	Fh	Default mode (load CFR with default value)	Don't care	Y	4	W

(1) The first four bits from SDO after the falling edge of $\overline{FS}/\overline{CS}$ are the four MSBs from the previous conversion result. The next 12 bits from SDO are the contents of the CFR.

(2) These commands apply only to the ADS8332; they are reserved (not available) for the ADS8331.

8.5.2 Writing to the Converter

There are two different types of writes to the register: a 4-bit write to the CMR and a full 16-bit write to the CMR plus CFR. The command set is listed in [Table 4](#) and the configuration register map is listed in [Table 5](#). A simple command requires only four SCLKs; the write takes effect on the fourth falling edge of SCLK. A 16-bit write or read takes at least 16 SCLKs (see [Table 7](#) for exceptions that require more than 16 SCLKs).

8.5.2.1 Configuring the Converter and Default Mode

The converter can be configured with command 1110b (write to the CFR) or command 1111b (default mode). A write to the CFR requires a 4-bit command followed by 12 bits of data. A 4-bit command takes effect on the fourth falling edge of SCLK. A write to the CFR takes effect on the 16th falling edge of SCLK.

The CFR default value for each bit is 1. The default values are applied to the CFR after issuing command 1111b or when the device is reset with a power-on reset (POR), software reset, or external reset using the **RESET** pin (see the [Reset Function](#) section).

The communication protocol of the ADS833x is full duplex. That is, data are transmitted to and from the device simultaneously. For example, the input mux channel can be changed via the SDI pin while data are being read through the SDO pin. All commands, except *Read CFR*, output conversion data on the SDO pin. If a *Read CFR* command is issued, the *Read Data* command can then be used to read back the conversion result.

8.5.3 Reading the Configuration Register

The host processor can read back the value programmed in the CFR by issuing command 1100b. The timing is similar to reading a conversion result except CONVST is not used. There is also no activity on the EOC/INT pin. The CFR value readback contains the first four bits (MSBs) of the previous conversion data plus the 12-bit CFR contents.

Table 5. Configuration Register (CFR) Map

CFR SDI BIT (Default = FFFh)	DEFINITION	BIT = 0	BIT = 1
D11	Channel select mode	Manual channel select enabled. Use channel select commands to access a desired channel.	Auto channel select enabled. Channels are sampled and converted sequentially until the cycle after this bit is set to 0.
D10	Conversion clock (CCLK) source select	Conversion clock (CCLK) = SCLK/2	Conversion clock (CCLK) = internal OSC
D9	Trigger (conversion start) select: start conversion at the end of sampling (EOS). If D9 = 0 and D8 = 0, the D4 setting is ignored.	Auto-Trigger: conversions automatically start three conversion clocks after EOC at 500 kSPS	Manual-Trigger: conversions manually start on falling edge of CONVST
D8	Sample rate for Auto-Trigger mode	500kSPS (21 CCLKs)	250 kSPS (42 CCLKs)
D7	Pin 10 polarity select when used as an output (EOC/INT)	EOC/INT active high	EOC/INT active low
D6	Pin 10 function select when used as an output (EOC/INT)	Pin used as INT	Pin used as EOC
D5	Pin 10 I/O select for daisy-chain mode operation	Pin 10 is used as CDI input (daisy-chain mode enabled)	Pin 10 is used as EOC/INT output
D4	Auto-NAP Power-Down enable/disable. This bit setting is ignored if D9 = 0 and D8 = 0.	Auto-NAP Power-Down mode enabled (not activated)	Auto-NAP Power-Down mode disabled
D3	Nap Power Down. This bit is set to 1 automatically by wake-up command.	Nap Power-Down enabled	Nap Power-Down disabled (resume normal operation)
D2	Deep Power Down. This bit is set to 1 automatically by wake-up command.	Deep Power-Down enabled	Deep Power-Down disabled (resume normal operation)
D1	TAG bit output enable	TAG bit output disabled	TAG bit output enabled. TAG bits appear after conversion data
D0	Software reset	System reset, returns to 1 automatically	Normal operation

8.5.4 Reading the Conversion Result

The conversion result is available to the input of the output data register (ODR) at EOC and presented to the output of the output register at the next falling edge of FS/CS. The host processor can then shift the data out through the SDO pin at any time except during the quiet zone. This duration is 20 ns before and 20 ns after the end of sampling (EOS) period. End of sampling (EOS) is defined as the falling edge of $\overline{\text{CONVST}}$ when Manual-Trigger mode is used or the end of the third conversion clock (CCLK) after EOC if Auto-Trigger mode is used.

The falling edge of FS/CS should not be placed at the precise moment at the end of a conversion (by default when EOC goes high). Otherwise, the data could be corrupt. If FS/CS is placed before the end of a conversion, the previous conversion result is read. If FS/CS is placed after the end of a conversion, the current conversion result is read.

The conversion result is 16-bit data in straight binary format as shown in Table 6. Generally 16 SCLKs are necessary, but there are exceptions when more than 16 SCLKs are required (see Table 7). Data output from the serial output (SDO) is left-adjusted MSB first. The trailing bits are filled with three TAG bits first (if enabled) plus all 0s. SDO remains low until FS/CS is brought high again.

SDO is active when FS/CS is low. The rising edge of FS/CS 3-states the SDO output.

NOTE

Whenever SDO is not in 3-state (that is, when FS/CS is low and SCLK is running), a portion of the conversion result is output at the SDO pin. The number of bits depends on how many SCLKs are supplied. For example, a manual channel select command cycle requires 4 SCLKs. Therefore, four MSBs of the conversion result are output at SDO. The exception is when SDO outputs all 1s during the cycle immediately after any reset (POR, software reset, or external reset).

If SCLK is used as the conversion clock (CCLK) and a continuous SCLK is used, it is not possible to clock out all 16 bits from SDO during the sampling time (6 SCLKs) because of the quiet zone requirement. In this case, it is better to read the conversion result during the conversion time (36 SCLKs or 48 SCLKs in Auto-NAP mode).

Table 6. Ideal Input Voltages and Output Codes

DESCRIPTION	ANALOG VALUE	DIGITAL OUTPUT STRAIGHT BINARY	
		BINARY CODE	HEX CODE
Full-scale range	V_{REF}	—	—
Least significant bit (LSB)	$V_{\text{REF}}/65536$	—	—
Full-scale	$V_{\text{REF}} - 1 \text{ LSB}$	1111 1111 1111 1111	FFFF
Midscale	$V_{\text{REF}}/2$	1000 0000 0000 0000	8000
Midscale – 1 LSB	$V_{\text{REF}}/2 - 1 \text{ LSB}$	0111 1111 1111 1111	7FFF
Zero	0 V	0000 0000 0000 0000	0000

8.5.4.1 TAG Mode

The ADS833x includes a TAG feature that can be used to indicate which channel sourced the converted result. If TAG mode is enabled, three address bits are added after the LSB of the conversion data is read out from SDO to indicate which channel corresponds to the result. These address bits are 000 for channel 0, 001 for channel 1, 010 for channel 2, 011 for channel 3, 100 for channel 4, 101 for channel 5, 110 for channel 6, and 111 for channel 7. The converter requires at least 19 SCLKs when TAG mode is enabled to transfer the 16-bit conversion result and the three TAG bits.

8.5.4.2 Daisy-Chain Mode

The ADS833x can operate as a single converter or in a system with multiple converters. System designers can take advantage of the simple, high-speed, SPI-compatible serial interface by cascading converters in a single chain when multiple converters are used. The CFR_D5 bit in the Configuration register is used to reconfigure the EOC/INT status pin as the chain data input (CDI) pin, a secondary serial data input, for the conversion result from an upstream converter. This configuration is called *daisy-chain mode* operation. A typical connection of three converters in daisy-chain mode is shown in Figure 46.

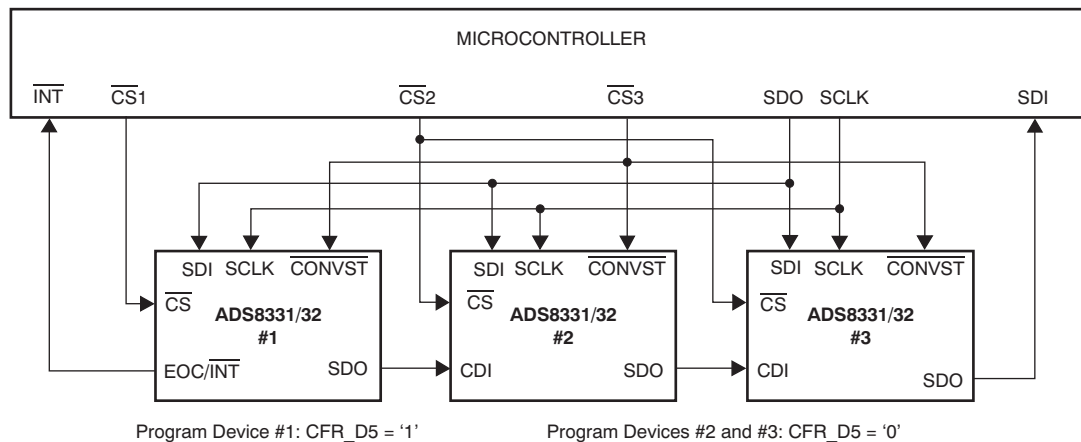

Figure 46. Multiple Converters Connected Using Daisy-Chain Mode

When multiple converters are used in daisy-chain mode, the first converter is configured in regular mode while the rest of the converters downstream are configured in daisy-chain mode. When a converter is configured in daisy-chain mode, the CDI input data go straight to the output register. Therefore, the serial input data passes through the converter with either a 16 SCLK (if the TAG feature is disabled) or 24-SCLK delay, as long as $\overline{\text{CS}}$ is active. See Figure 47 for detailed timing. In this timing diagram, the conversion in each converter is performed simultaneously.

Manual Trigger, Read While Sampling
(Use internal CCLK, EOC active low, and TAG mode disabled)

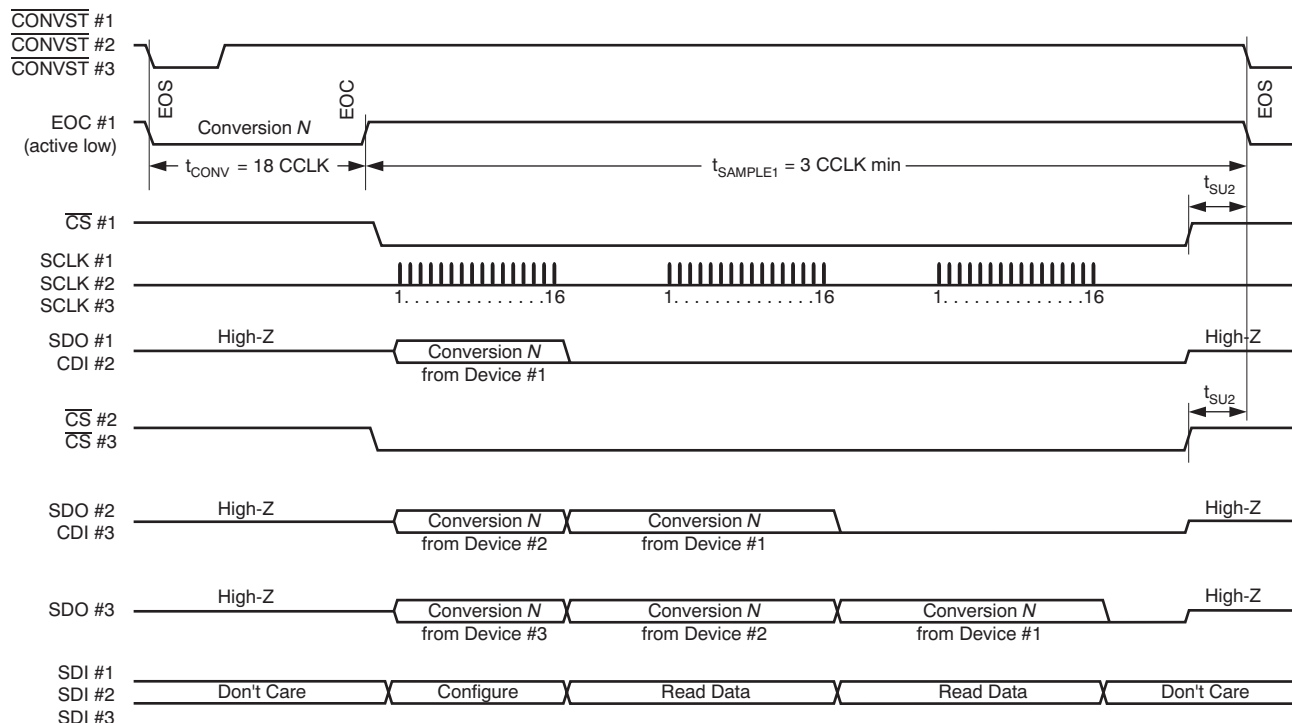

Figure 47. Simplified Daisy-Chain Mode Timing With Shared $\overline{\text{CONVST}}$ and Continuous $\overline{\text{CS}}$

The multiple $\overline{\text{CS}}$ signals must be handled with care when the converters are operating in daisy-chain mode. The different chip select signals must be low for the entire data transfer (in this example, 48 bits for three conversions). The first 16-bit word after the falling chip select is always the data from the chip that received the chip select signal.

Case 1: If chip select is not toggled (\overline{CS} stays low), the next 16 bits of data are from the upstream converter, and so on. This configuration is shown in Figure 47.

Case 2: If the chip select is toggled during a daisy-chain mode data transfer cycle, as illustrated in Figure 48, the same data from the converter are read out again and again in all three discrete 16-bit cycles. This state is **not** a desired result.

Manual Trigger, Read While Sampling
(Use internal CCLK, EOC active low, and TAG mode disabled)

Figure 48. Simplified Daisy-Chain Mode Timing With Shared \overline{CONVST} and Noncontinuous \overline{CS}

Figure 49 shows a slightly different scenario where $\overline{\text{CONVST}}$ is not shared with the second converter. Converters #1 and #3 have the same $\overline{\text{CONVST}}$ signal. In this case, converter #2 simply passes previous conversion data downstream.

Manual Trigger, Read While Sampling
(Use internal CCLK, EOC active low, and TAG mode disabled)

(1) Data from device #2 is from previous conversion.

Figure 49. Simplified Daisy-Chain Mode Timing with Separate $\overline{\text{CONVST}}$ and Continuous $\overline{\text{CS}}$

The number of SCLKs required for a serial read cycle depends on the combination of different read modes, TAG mode, daisy-chain mode, and the manner in which a channel is selected (for example, Auto Channel Select mode). The required number of SCLKs for different readout modes are listed in Table 7.

Table 7. Required SCLKs for Different Readout Mode Combinations

DAISY-CHAIN MODE CFR_D5	TAG MODE CFR_D1	NUMBER OF SCLK CYCLES PER SPI READ	TRAILING BITS
1	0	16	None
1	1	≥ 19	TAG bits plus up to 5 zeros
0	0	16	None
0	1	24	TAG bits plus 5 zeros

SCLK skew between converters in a daisy-chain configuration can affect the maximum frequency of SCLK. The skew can also be affected by supply voltage and loading. It may be necessary to slow down the SCLK when the devices are configured in daisy-chain mode.

8.5.5 Reset Function

The ADS833x can be reset with three different methods: internal POR, software reset, and external reset using the RESET pin.

The internal POR circuit is activated when power is initially applied to the converter. This internal circuit eliminates the need for commands to be sent to the converter after power on to set the default mode of operation (see the [Power-On Sequence Timing](#) section for further details).

Software reset can be used to place the converter in the default mode by setting the CFR_D0 bit to 0 in the Configuration register (see [Table 5](#)). This bit is automatically returned to 1 (default) after the converter is reset. This reset method is useful in systems that cannot dedicate a separate control signal to the $\overline{\text{RESET}}$ pin. In these situations, the RESET pin must be connected to VBD for the ADS833x to operate properly.

If communication in the system becomes corrupted and a software reset cannot be issued, the $\overline{\text{RESET}}$ pin can be used to reset the device manually. To reset the device and return the device to default mode, this pin must held low for a minimum of 25 ns.

After the ADS833x detects a reset condition, the minimum time before the device can be reconfigured by FS/ $\overline{\text{CS}}$ going low and data clocking in on SDI is 2 μs .

9 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The two primary circuits required to optimize the performance of a high-precision, successive approximation register (SAR), analog-to-digital converter (ADC) are the input driver and the reference driver circuits. This section details some general principles for designing these circuits, and some application circuits designed using these devices.

9.1.1 ADC Reference Driver

The reference source to the ADC must provide low drift, very accurate DC voltage and support the dynamic charge requirements without affecting the noise and linearity performance of the device. The output broadband noise (typically in the order of a few 100 μV_{RMS}) of the reference source must be appropriately filtered by using a low pass filter with a cut-off frequency of a few hundred hertz. After band-limiting the noise from the reference source, the next important step is to design a reference buffer that can drive the dynamic load posed by the reference input of the ADC. At the start of each conversion, the reference buffer must regulate the voltage of the reference pin within 1 LSB of the intended value. This condition necessitates the use of a large 22- μF bypass capacitor at the reference pin of the ADC. The amplifier selected to drive the reference input pin must be stable while driving this large capacitor and should have low output impedance, low offset, and temperature drift specifications.

9.1.1.1 Reference Driver Circuit for $V_{\text{REF}} = 4.096 \text{ V}$

The application circuit in [Figure 50](#) shows the schematic of a complete reference driver circuit that generates a voltage of 4.096-V DC using a single 5-V supply. This circuit is suitable to drive the reference of the ADS8332 at the maximum throughput of 500 kSPS. The reference voltage of 4.096 V in this design is generated by the low-power, low drift, low-power [REF2041](#) circuit. The output broadband noise of the reference is filtered by a low-pass filter with a 3-dB cutoff frequency of 159 Hz.

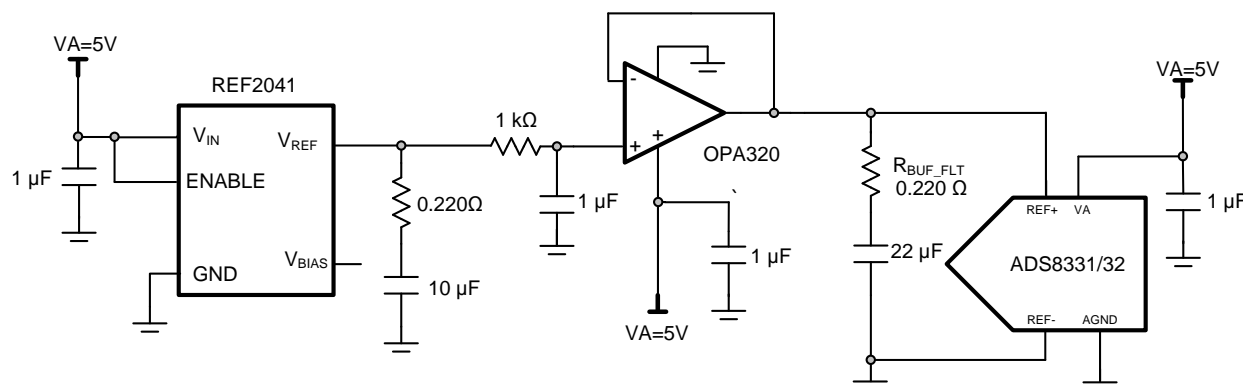

Figure 50. Reference Driver Schematic for $V_A = 5 \text{ V}$, $V_{\text{REF}} = 4.096 \text{ V}$

The [OPA320](#) is a precision, high bandwidth (20 MHz), low-noise (7 nV/ $\sqrt{\text{Hz}}$) operational amplifier. The low-noise, and low power consumption of this amplifier makes the OPA320 a good choice to drive the reference input of the ADS833x. The REF+ input is bypassed with a 22- μF bypass capacitor. The 22- μF reference bypass capacitor is high enough to make the OPA320 amplifier unstable, therefore a small resistor ($R_{\text{BUF_FLT}}$) is required to isolate the amplifier output and improve stability. The value of $R_{\text{BUF_FLT}}$ is dependent on the output impedance of the

Application Information (continued)

driving amplifier as well as the circuit frequency response. Typical values of R_{BUF_FLT} range from $0.1\ \Omega$ to $2\ \Omega$ and the exact value can be found by using SPICE simulations. In the case of the OPA320 in the reference driver example in Figure 50, the value of R_{BUF_FLT} is $220\ m\Omega$ providing $>55^\circ$ of phase margin while driving the $22\text{-}\mu\text{F}$ bypass capacitor. It should be noted that higher values of R_{BUF_FLT} cause high voltage spikes at the reference pin which affects the conversion accuracy.

9.1.1.2 Reference Driver Circuit for $V_{REF}=2.5\ \text{V}$, $V_A=2.7\ \text{V}$

The circuit shown in Figure 51 can be used to generate a 3-V reference using a 3.3-V supply. This circuit is suitable to drive the reference of the ADS8332 at the maximum throughput of 500 kSPS. The reference voltage of 3 V in this design is generated by the low-power, low drift, REF2025. The output broadband noise of the reference is filtered by a low-pass filter with a 3-dB cutoff frequency of 159 Hz.

Figure 51. Reference Driver Schematic for $V_A = 2.7\ \text{V}$, $V_{REF} = 2.5\ \text{V}$

9.1.2 ADC Input Driver

To take advantage of the high sample rate offered by the ADS833x, the analog inputs (INx) of the device should be driven with low noise operational amplifiers. The optimal input driver circuit for a high precision SAR ADC consists of a driving amplifier and a fly-wheel RC filter. The amplifier driving the ADC must have low output impedance and be able to charge the internal sampling capacitor (45pF) to a 16-bit settling level within the minimum acquisition time. The RC filter helps attenuate the sampling charge injection from the switched-capacitor input stage of the ADC and helps to reduce the wideband noise contributed by the front-end circuit. Careful design of the front-end circuit is critical to meet the linearity and noise performance of a high-precision ADC.

9.1.2.1 Input Amplifier Selection

The selection criteria for the input driver amplifier is dependent on the input signal type and the performance goals of the data acquisition system. Some key amplifier specifications to consider while selecting an appropriate amplifier to drive the inputs of the ADC are:

- **Small-signal bandwidth:** Select the small-signal bandwidth of the input amplifiers to be as high as possible after meeting the power budget of the system. Higher bandwidth reduces the closed-loop output impedance of the amplifier, thus allowing the amplifier to more easily drive the RC filter at the ADC inputs. Higher bandwidth also minimizes the harmonic distortion at higher input frequencies. To maintain the overall stability of the input driver circuit, the amplifier bandwidth should be selected as described in Equation 2:

$$\text{Unity – Gain Bandwidth} \geq 4 \times \left(\frac{1}{2\pi \times R_{FLT} \times C_{FLT}} \right) \quad (2)$$

- **Noise:** Noise contribution of the front-end amplifiers should be as low as possible to prevent any degradation in SNR performance of the system. As a rule of thumb, to ensure that the noise performance of the data acquisition system is not limited by the front-end circuit, the total noise contribution from the front-end circuit should be kept below 20% of the input-referred noise of the ADC. Noise from the input driver circuit is band-limited by designing a low cutoff frequency RC filter and is calculated by Equation 3:

Application Information (continued)

$$NG \times \sqrt{\left(\frac{V_{1/f_AMP_PP}}{6.6}\right)^2 + e_{n_REF_RMS}^2 \times \frac{\pi}{2} \times f_{REF_3dB}} \leq \frac{1}{3} \times \frac{V_{FSR}}{2\sqrt{2}} \times 10^{\frac{SNR(dB)}{20}}$$

where

- V_{1/f_AMP_PP} is the peak-to-peak flicker noise in μV
 - e_{n_RMS} is the amplifier broadband noise density in nV/\sqrt{Hz}
 - f_{3dB} is the 3-dB bandwidth of the RC filter
 - NG is the noise gain of the front-end circuit, which is equal to 1 in a buffer configuration (3)
- **Distortion:** Both the ADC and the input driver introduce non-linearity in a data acquisition block. As a rule of thumb, to ensure that the distortion performance of the data acquisition system is not limited by the front-end circuit, the distortion of the input driver should be at least 10-dB lower than the distortion of the ADC, as shown in [Equation 4](#):

$$THD_{AMP} \leq THD_{ADC} - 10(dB) \quad (4)$$
 - **Settling Time:** For DC signals with fast transients that are common in a multiplexed application, the input signal must settle to the desired accuracy at the inputs of the ADC during the acquisition time window. This condition is critical to maintain the overall linearity performance of the ADC. Typically, the amplifier data sheets specify the output settling performance only up to 0.01% with a resistive load which may not be sufficient for the desired accuracy. Therefore, the settling behavior of the input driver with the RC filter load should always be verified by TINA™- SPICE simulations before selecting the amplifier.

9.1.2.2 ADC Input RC Filter

An RC filter is designed as a low-pass, RC filter, for which the 3-dB bandwidth is optimized based on specific application requirements. For DC signals with fast transients (including multiplexed input signals), a high-bandwidth filter is designed to allow accurate settling of the signal at the ADC inputs during the small acquisition time window. For AC signals, the filter bandwidth should be kept low to band-limit the noise fed into the ADC input, thereby increasing the signal-to-noise ratio (SNR) of the system.

A filter capacitor, C_{FLT} , connected across the ADC inputs (as shown in [Figure 52](#)), reduces the noise from the front-end drive circuitry, minimizes the effects of the sampling charge injection and provides a charge bucket to quickly charge the internal sample-and-hold capacitors during the acquisition process. As a rule of thumb, the value of this capacitor should be at least 10 times the specified value of the ADC sampling capacitance. For these devices, the input sampling capacitance is equal to 45 pF. Thus, the value of C_{FLT} should be greater than 450 pF. For applications measuring AC signals, COG (NPO) ceramic capacitors provide the best capacitance precision. The type of dielectric used in COG (NPO) ceramic capacitors provides the most stable electrical properties over voltage, frequency, and temperature changes.

Driving capacitive loads can degrade the phase margin of the input amplifiers, thus making the amplifier marginally unstable. To avoid amplifier stability issues, series isolation resistors (R_{FLT}) are used at the output of the amplifiers. A higher value of R_{FLT} is helpful from the amplifier stability perspective, but adds distortion as a result of interactions with the nonlinear input impedance of the ADC. Distortion increases with source impedance, input signal frequency, and input signal amplitude. Therefore, the selection of R_{FLT} requires balancing the stability and distortion of the design. For low distortion applications, TI recommends limiting the value of R_{FLT} to a maximum of 50 Ω to avoid any significant degradation in linearity and THD performance.

The input amplifier bandwidth should be much higher than the cutoff frequency of the anti-aliasing filter. TI strongly recommends performing a SPICE simulation to confirm that the amplifier has more than 40° phase margin with the selected RC filter.

Application Information (continued)

Figure 52. ADC Input RC Filter

9.2 Typical Application

9.2.1 DAQ Circuit for Low Noise and Distortion Performance for a 10-kHz Input Signal at 500 kSPS

Figure 53 illustrates a typical data acquisition circuit using the ADS833x for the lowest noise and distortion performance using a 10-kHz input signal at 500 kSPS.

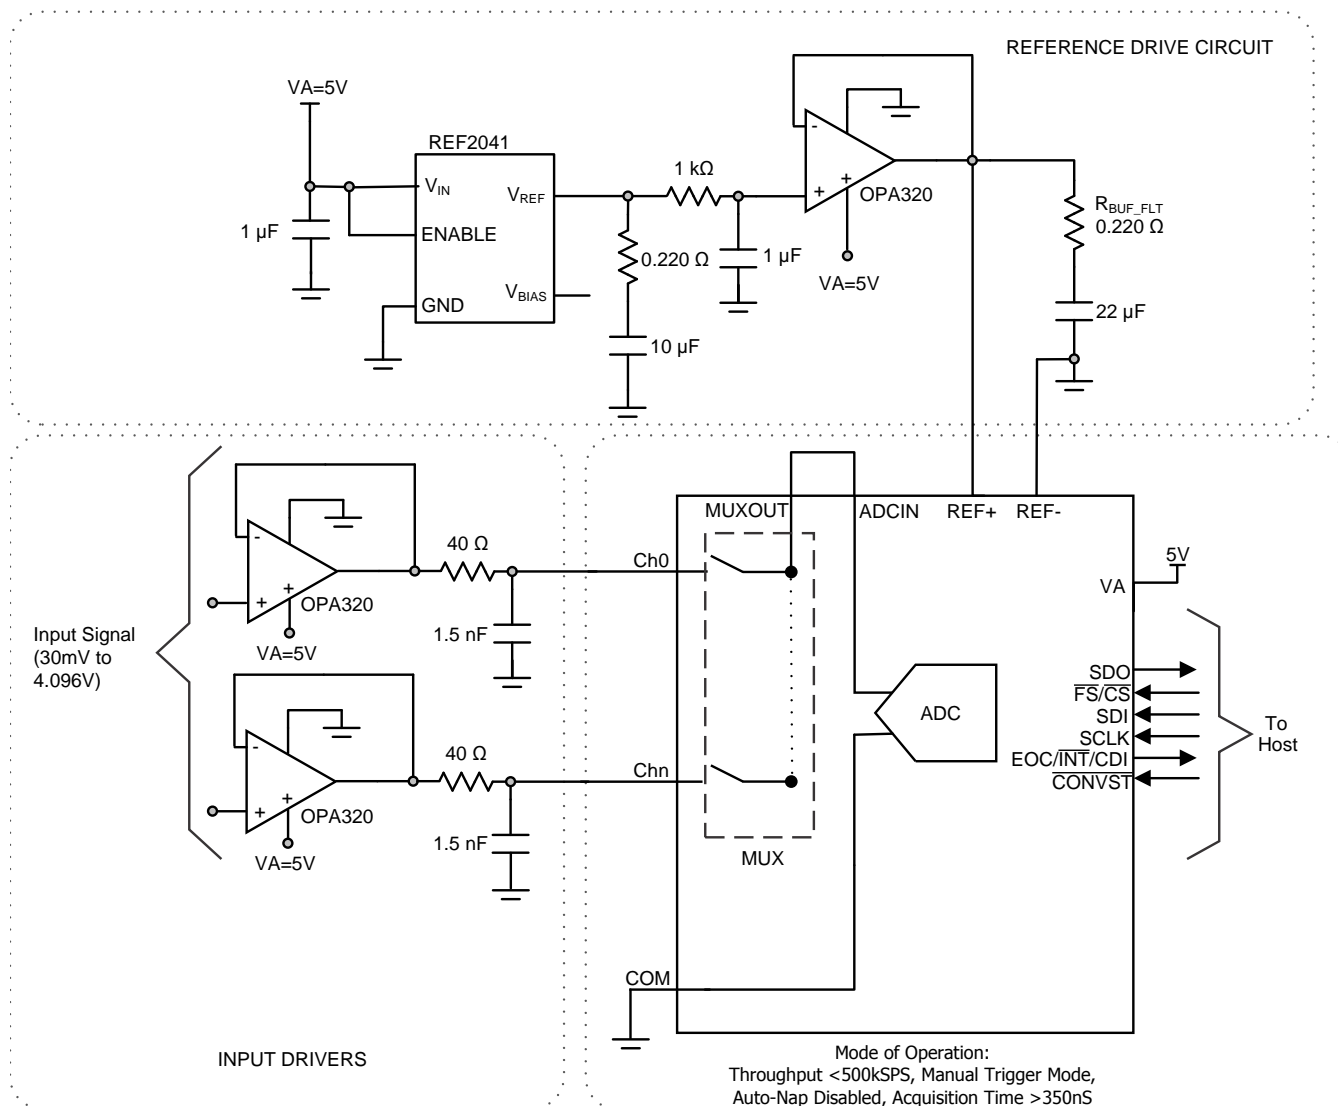

Figure 53. Typical Circuit Configuration

9.2.1.1 Design Requirements

This section describes an application circuit (Figure 53) optimized for using the ADS833x with lowest noise and distortion performance at ADC throughput of 500kSPS across all channels, using Manual Trigger mode with Auto-Nap mode disabled. The throughput per channel is dependent on the number of channels selected in the multiplexer scanning sequence. For example, the throughput per channel is equal to 250 kSPS if two channels are selected, but it is equal to 125 kSPS per channel if four channels are selected in the sequence and so forth.

Typical Application (continued)

9.2.1.2 Detailed Design Procedure

The signal is processed by a low noise, low distortion, operational amplifier in the non-inverting configuration and a low-pass RC filter before being fed into the ADC. The OPA320 features rail-to-rail input operation with a zero-crossover distortion topology that eliminates the transition region typical in many rail-to-rail complementary input stage amplifiers making it ideal to use in the non-inverting configuration. As a rule of thumb, the distortion from the input driver should be at least 10-dB less than the ADC distortion. Therefore, the driver circuit uses the low-power, wide bandwidth (20 MHz) OPA320 as an input driver, which provides exceptional AC performance because of its low-noise, and low distortion specifications. In addition, the components of the RC filter are selected such that the noise from the front-end circuit is limited without adding distortion to the input signal. [Driver Amplifier Choice](#) lists some more driver amplifier choices for applications that require high throughput operation with minimum acquisition time.

9.2.1.3 Application Curve

[Figure 54](#) shows the FFT test results obtained with the ADS833x operating at full throughput of 500 kSPS and the circuit configuration of [Figure 53](#).

Figure 54. FFT Plot Showing Performance of ADS8331/2 With a 10-kHz Input Signal at 500 kSPS

Typical Application (continued)

9.2.2 Ultra Low-Power DAQ Circuit for DC Input Signals at 10 kSPS per Channel

Figure 55 illustrates a typical data acquisition circuit that is optimized for using the ADS833x in low power, low throughput applications for monitoring static or DC signals.

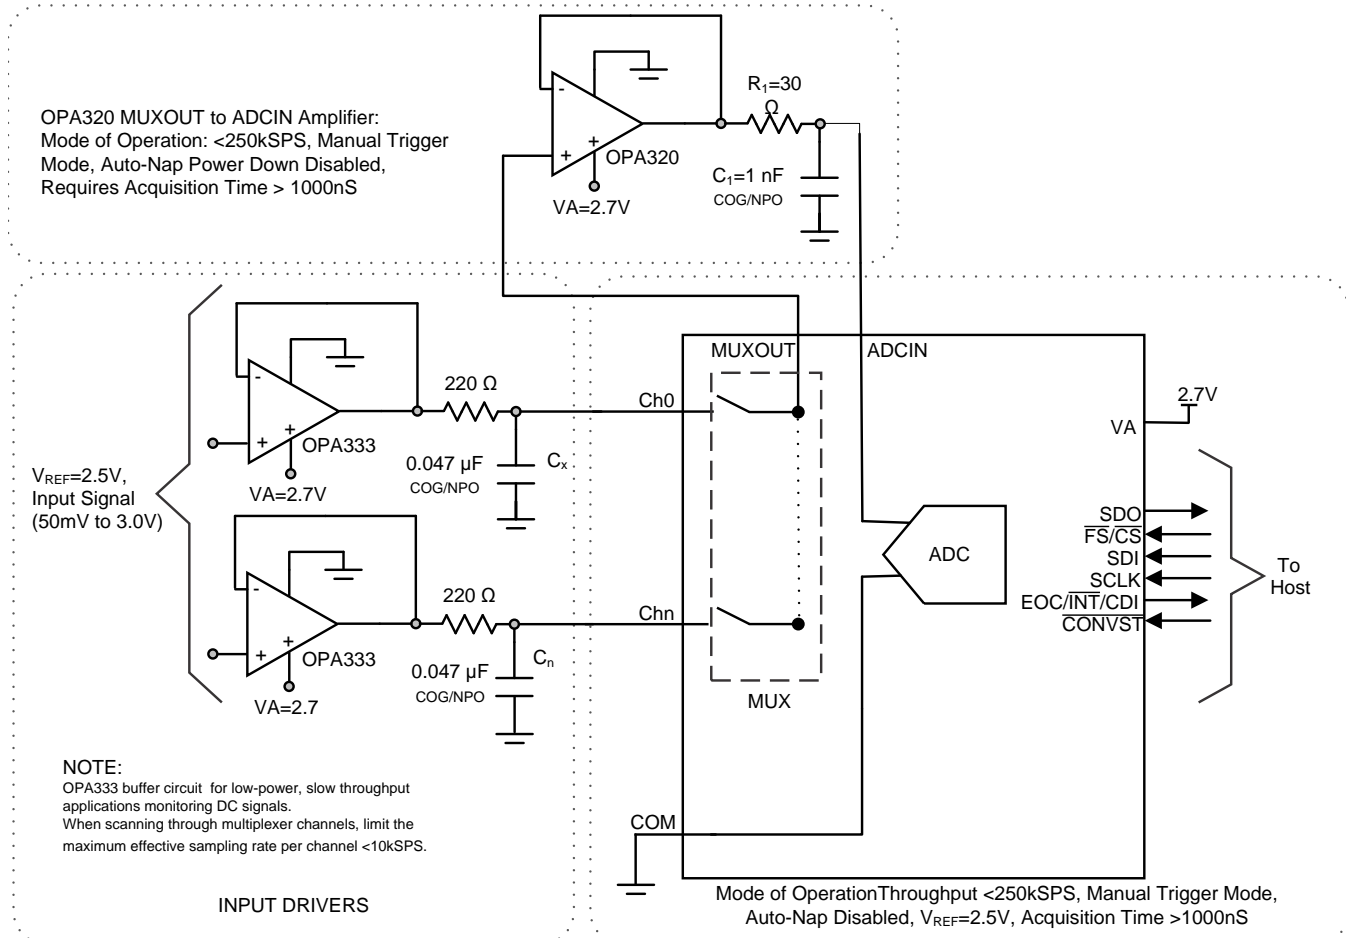

Figure 55. Typical Circuit Configuration

9.2.2.1 Design Requirements

This section describes an application circuit (Figure 55) optimized for using the ADS8332 in low power, low throughput applications for monitoring static or DC signals. A single OPA320 amplifier and passive filter (R₁, C₁) is placed between the MUXOUT and ADCIN inputs driving the ADS8332, while operating the ADC at a reduced data rate.

9.2.2.2 Detailed Design Procedure

The ADS833x offers the flexibility to place an amplifier between the MUXOUT and ADCIN pins. In this case, the operational amplifier between the multiplexer output and ADC input pin must have optimum transient response to charge the internal sampling capacitor (45 pF) and settle within 1 LSB after a full-scale step within the allowed acquisition time.

Typical Application (continued)

Placing an amplifier as a buffer between the multiplexer output and the ADC input helps to relax the source impedance requirements at the IN_x multiplexer inputs. However, it should be noted that there is a parasitic capacitance associated with the MUXOUT pin (approximately 5 pF). This is in addition to the input capacitance of the buffer amplifier placed between MUXOUT and ADCIN pins. This capacitance is switched from one channel to the next during the scan operation and must be recharged to new input channel voltage every time the multiplexer switches channels. Therefore, take care so the previously converted channel charge stored at the MUXOUT capacitance does not disturb the charge of the newly switched channel. This error can be reduced by placing a large enough capacitor at each (IN_x) multiplexer input.

The data acquisition circuit in [Figure 55](#) is optimized for using the ADS8332 in low power, low throughput applications for monitoring static or DC signals. A single OPA320 amplifier and passive filter (R₁, C₁) is placed between the MUXOUT and ADCIN inputs driving the ADS8332, while operating the ADC at a reduced data rate. The OPA320 offers optimal settling time, DC precision and low noise at a relatively low power consumption (1.5 mA). In this case, the R1C1 filter is designed to settle within ± 1 LSB in less than 1 μ S after a full-scale input is applied. The ADC is operating at a reduced data rate of less than 250 kSPS in Manual Trigger Mode with Auto-NAP disabled (inactive) to allow a longer acquisition time.

Each multiplexer input is buffered with an ultralow power OPA333 to isolate the source impedance at the multiplexer inputs. A large capacitor C_x is placed at each IN_x input. The OPA320 has an estimated input capacitance of approximately 9 pF, and the capacitance associated with the MUXOUT pin is approximately 5 pF. The C_x capacitor is many times larger than the parasitic capacitance present at the MUXOUT pin to reduce the effect of charge injection due to the previously converted channel. The OPA333 consumes a maximum quiescent current of 25 μ A per amplifier while providing low drift, excellent stability and DC performance at ultra low power consumption. To save power, this circuit is operated on a single 2.7-V supply. The OPA333 circuit is optimal for low-power, low-throughput applications measuring DC signals. When scanning through multiplexer channels ensure to limit the maximum sampling rate per channel to <10kSPS.

10 Power Supply Recommendations

During power on of the ADS833x, the digital interface supply voltage (V_{DD}) should not exceed the analog supply voltage (V_A). This condition is specified in the *Power-Supply Requirements* section of the Electrical Characteristics tables. If the analog and digital interface supplies for the converter are not generated by a single voltage source, TI recommends to power on the analog supply and wait for it to reach its final value before the digital interface supply is activated. Furthermore, the voltages applied to the analog input pins (IN_x, ADCIN) and digital input pins (RESET, FS/CS, SCLK, SDI, and CONVST) should not exceed the voltages on V_A and V_{DD}, respectively, during the power-on sequence. This requirement prevents these input pins from powering the ADS833x through the ESD protection diodes/circuitry, and causing an increase in current consumption, until both supplies are fully powered (see the Electrical Characteristics and [Figure 34](#) for further details).

Communication with the ADS833x, such as initiating a conversion with $\overline{\text{CONVST}}$ or writing to the Configuration register, should not occur for a minimum of 2 μ s after the analog and digital interface supplies have finished the power-on sequence and reached the respective final values in the system. This time is required for the internal POR to activate and place the digital core of the device into the default mode of operation. This minimum delay time must also be adhered to whenever a reset condition occurs (see the [Reset Function](#) section for additional information).

11 Layout

11.1 Layout Guidelines

[Figure 56](#) shows a board layout example for the ADS833x with the VQFN package. Use a ground plane underneath the device and partition the PCB into analog and digital sections. Avoid crossing digital lines with the analog signal path and keep the analog input signals and the reference input signals away from noise sources. As shown in [Figure 56](#), the analog input and reference signals are routed on the left side of the board and the digital connections are routed on the right side of the device.

Layout Guidelines (continued)

The power sources to the device must be clean and well-bypassed. Use 10 μF , ceramic bypass capacitors in close proximity to the analog (VA) and digital (VBD) power-supply pins. Avoid placing vias between the AVDD and DVDD pins and the bypass capacitors. Connect all ground pins to the ground plane using short, low impedance paths.

The REF+ reference input is bypassed with a 22 μF , X7S-grade, 0805-size, 10-V rated ceramic capacitors. Place the reference bypass capacitor as close as possible to the reference REF+ and REF- pins and connect the bypass capacitor using short, low-inductance connections. Avoid placing vias between the REF+/REF- pins and the bypass capacitor. If the reference voltage originates from an op amp, make sure that the op amp can drive the bypass capacitor without oscillation. A small 0.2- Ω to 0.5- Ω resistors (R_{REF}) is used in series with the reference bypass capacitor to improve stability.

The fly-wheel RC filters are placed immediately next to the input pins. For applications measuring AC signals, COG (NPO) ceramic capacitors provide the best capacitance precision. [Figure 56](#) shows input filter capacitors placed in close proximity to the INx analog input pins of the device.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBsolete: TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

TBD: The Pb-Free/Green conversion plan has not been defined.

Pb-Free (RoHS): TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

Pb-Free (RoHS Exempt): This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

THERMAL PAD MECHANICAL DATA

RGE (S-PVQFN-N24)

PLASTIC QUAD FLATPACK NO-LEAD

THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
